

Where the non-additivity comes from — Temperature, 2041–2050
 additive inputs, non-additive response: the model manufactures R rather than reading it off the conditioning

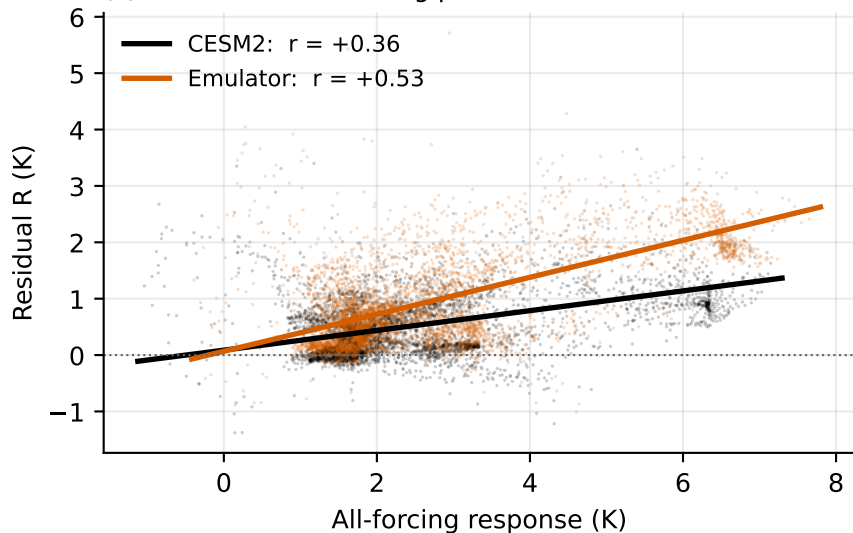

(a) The INPUT is additive
 conditioning channels, 2041–2050 mean

(b) The emulator's Arctic excess is three
 same-signed scenario biases, not one

(c) R is NOT the warming pattern rescaled

(d) R is ANTI-correlated with the aerosol response
 — aerosol efficacy falls in a warmer base state
