

Where the non-additivity comes from — Temperature, 2041-2050
additive inputs, non-additive response: the model manufactures R rather than reading it off the conditioning

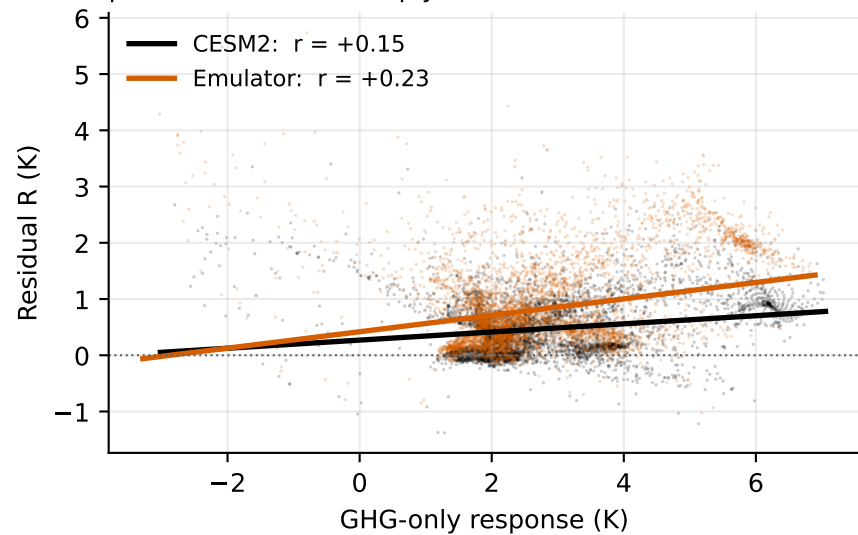

(a) The emulator's Arctic excess is three same-signed scenario biases, not one

(b) R is NOT the warming pattern rescaled

(c) vs the GHG-only response — the agent whose pattern R does not simply follow

(d) R is ANTI-correlated with the aerosol response — aerosol efficacy falls in a warmer base state
